- $\bullet$  (paragraph) Explanation of R package

## 2 Introduction: Predictive Inference

- 2.1 Why is predictive inference important?
- 2.2 Difference between parametric inference and predictive inference
- 2.2.1 When is predictive inference more useful?
- 2.2.2 When is parametric inference more useful?

[examples, comparisons]

## 2.3 The Bayesian Parametric Prediction Format

[Geisser p. 49]

Let

$$f\left(x^{(N)}, x_{(M)}|\theta\right) = f\left(x_{(M)}|x^{(N)}, \theta\right) f\left(x^{(N)}|\theta\right).$$

Here  $x^{(N)}$  represents observed events and  $x_{(M)}$  are future events. We calculate

$$f(x_{(M)}, x^{(N)}) = \int f(x^{(N)}, x_{(M)}|\theta) p(\theta) d\theta$$

where  $p(\theta)$  is the prior density and

$$f\left(x_{(M)}|x^{(N)}\right) = \frac{f\left(x_{(M)}, x^{(N)}\right)}{f\left(x^{(N)}\right)} = \int f\left(x_{(M)}|\theta\right) p\left(\theta|x^{(N)}\right) d\theta$$

where

$$p\left(\theta|x^{(N)}\right) \propto f\left(x^{(N)}|\theta\right)p(\theta).$$

2.4 [Maybe] Example of Difference between results from Plug-in estimator and results using Predictive Inference

## 3 Chapter 1: Predictive Problems with Conjugate Priors

[Problems with closed-form solutions. These problems will be what the R package is designed for. Use problems from Geisser, Casella & Berger (Bayesian chapter), other sources. Regression problem—predictive distributions of models that include and exclude some predictor]

## 3.1 Prediction of Future Successes: Beta-Binomial (Geisser p. 73)

## 3.1.1 Derivation

Let  $X_i$  be independent binary variables with  $\Pr(X_i = 1) = \theta$ , and let  $T = \sum X_i$ . Then T has probability

$$\binom{N}{t}\theta^t (1-\theta)^{N-t}.$$

Assume  $\theta \sim \text{Beta}(\alpha, \beta)$ , so

$$p(\theta) = \frac{\Gamma(\alpha + \beta)\theta^{\alpha - 1}(1 - \theta)^{\beta - 1}}{\Gamma(\alpha)\Gamma(\beta)}.$$

Then

$$p\left(\theta|X^{(N)}\right) = \frac{\Gamma(N+\alpha+\beta)\theta^{t+\alpha-1}(1-\theta)^{N-t+\beta-1}}{\Gamma(t+\alpha)\Gamma(N-t+\beta)}$$

So for  $R = \sum_{i=1}^{M} X_{N+i}$  we have Beta-Binomial predictive distribution

$$\Pr[R = r|t] = \int \binom{M}{r} \theta^r (1-\theta)^{M-r} p\left(\theta|X^{(N)}\right) d\theta$$

$$= \binom{M}{r} \int \theta^r (1-\theta)^{M-r} \frac{\Gamma(N+\alpha+\beta)}{\Gamma(t+\alpha)\Gamma(N-t+\beta)} \theta^{t+\alpha-1} (1-\theta)^{N-t+\beta-1} d\theta$$

$$= \frac{M!}{r!(M-r)!} \frac{\Gamma(N+\alpha+\beta)}{\Gamma(t+\alpha)\Gamma(N-t+\beta)} \int \theta^{r+t+\alpha-1} (1-\theta)^{M-r+N-t+\beta-1} d\theta$$

$$= \frac{\Gamma(M+1)\Gamma(N+\alpha+\beta)\Gamma(r+t+\alpha)\Gamma(M-r+N-t+\beta)}{\Gamma(r+1)\Gamma(M-r+1)\Gamma(t+\alpha)\Gamma(N-t+\beta)\Gamma(M+N+\alpha+\beta)}$$

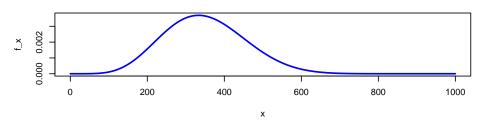

## 3.1.2 R Implementation

This result has been used to create "standard" R functions dpredBB(), ppredBB(), and rpredBB() for the Beta-Binomial distribution for density, cumulative probability, and random sampling, respectively (see appendix). These functions are exercised in the following example.

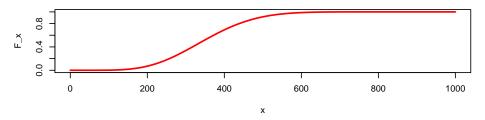

## 3.1.3 Example

Suppose t = 5 successes have been observed out of N = 10 binary events,  $\alpha = 2$  and  $\beta = 8$ . For M = 1000 future observations, the figures below show the predictive distribution from dpredBB(), the cumulative distribution from ppredBB(), and a histogram of random draws from rpredBB().

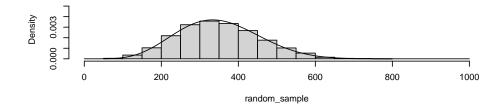

#### **Beta-Binomial Predictive Density**

#### **Beta-Binomial Cumulative Predictive Probability**

Histogram of Sample with Density Curve Overlay

## 3.2 Survival Time: Exponential-Gamma (Geisser p. 74)

## 3.2.1 Derivation

Suppose  $X^{(N)} = (X^{(d)}, X^{(N-d)})$  where  $X^{(d)}$  represents copies fully observed from an exponential survival time density

$$f(x|\theta) = \theta e^{-\theta x}$$

and  $X^{(N-d)}$  represents copies censored at  $x_{d+1},...,x_N$ , respectively. Hence

$$L(\theta) \propto \theta^d e^{-\theta N\bar{x}}$$

when  $N\bar{x} = \sum_{i=1}^{N} x_i$ , as shown below.

The usual exponential likelihood is used for the fully observed copies, whereas for the censored copies we need  $\Pr(x > \theta) = 1 - \Pr(x \le \theta) = 1 - F(x|\theta) = 1 - (1 - e^{-\theta x}) = e^{-\theta x}$ . Thus the overall likelihood is

$$L(\theta|x) = \prod_{i=1}^{d} \theta e^{-\theta x_i} \prod_{i=d+1}^{N} e^{-\theta x_i} = \theta^d e^{-\theta N\bar{x}}$$

Assuming a Gamma( $\delta, \gamma$ ) prior for  $\theta$ ,

$$p(\theta) = \frac{\gamma^{\delta} \theta^{\delta - 1} e^{-\gamma \theta}}{\Gamma(\delta)}$$

we obtain the posterior

$$p(\theta|X^{(N)}) = \frac{p(x^{(N)}|\theta)p(\theta)}{\int p(X^{(N)}|\theta)p(\theta)d\theta}$$

$$= \frac{\theta^{d}e^{-\theta N\bar{x}} \cdot \frac{\gamma^{\delta}\theta^{\delta-1}e^{-\gamma\theta}}{\Gamma(\delta)}}{\int \left(\theta^{d}e^{-\theta N\bar{x}} \cdot \frac{\gamma^{\delta}\theta^{\delta-1}e^{-\gamma\theta}}{\Gamma(\delta)}\right)d\theta}$$

$$= \frac{\frac{\gamma^{\delta}}{V(\delta)} \left(\theta^{d+\delta-1}e^{-\theta(\gamma+N\bar{x})}\right)}{\frac{\gamma^{\delta}}{V(\delta)} \int \left(\theta^{d+\delta-1}e^{-\theta(\gamma+N\bar{x})}\right)d\theta}$$

$$= \frac{\frac{(\gamma+N\bar{x})^{d+\delta}}{\Gamma(d+\delta)} \left(\theta^{d+\delta-1}e^{-\theta(\gamma+N\bar{x})}\right)d\theta}{\frac{(\gamma+N\bar{x})^{d+\delta}}{\Gamma(d+\delta)} \int \left(\theta^{d+\delta-1}e^{-\theta(\gamma+N\bar{x})}\right)d\theta}$$

$$= \frac{(\gamma+N\bar{x})^{d+\delta}}{\Gamma(d+\delta)} \int \left(\theta^{d+\delta-1}e^{-\theta(\gamma+N\bar{x})}\right)d\theta}$$

$$= \frac{(\gamma+N\bar{x})^{d+\delta}\theta^{d+\delta-1}e^{-\theta(\gamma+N\bar{x})}}{\Gamma(d+\delta)}$$

with the Gamma $(d + \delta, \gamma + N\bar{x})$  density in the next to last step integrating to 1.

Thus the survival time predictive probability is

$$P(X = x | \theta, X^{(N)}) = \int p(\theta | X^{(N)}) p(x | \theta) d\theta$$

$$= \int \frac{(\gamma + N\bar{x})^{d+\delta} \theta^{d+\delta-1} e^{-\theta(\gamma + N\bar{x})}}{\Gamma(d+\delta)} \cdot \theta e^{-\theta x} d\theta$$

$$= (d+\delta)(\gamma + N\bar{x})^{d+\delta} \int \frac{\theta^{(d+\delta+1)-1} e^{-\theta(\gamma + N\bar{x} + x)}}{(d+\delta)\Gamma(d+\delta)} d\theta$$

$$= \frac{(d+\delta)(\gamma + N\bar{x})^{d+\delta}}{(\gamma + N\bar{x} + x)^{d+\delta+1}} \int \frac{(\gamma + N\bar{x} + x)^{d+\delta+1} \theta^{(d+\delta+1)-1} e^{-\theta(\gamma + N\bar{x} + x)}}{\Gamma(d+\delta + 1)} d\theta$$

$$= \frac{(d+\delta)(\gamma + N\bar{x})^{d+\delta}}{(\gamma + N\bar{x} + x)^{d+\delta+1}}$$

(simplifying by constructing a Gamma $(d + \delta + 1, \gamma + N\bar{x} + x)$  density in the final integrand.)

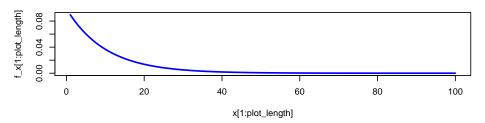

## 3.2.2 R Implementation

This result has been used to create standard format R functions dpredEG(), ppredEG(), and rpredEG() for the Gamma-Exponential distribution for density, cumulative probability, and random sampling, respectively (see appendix). These functions are exercised in the following example.

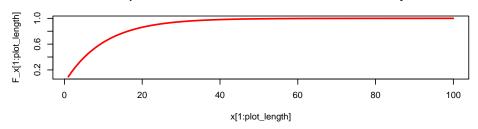

#### **3.2.3** Example

Suppose d=800 out of N=1000 copies have been observed, and the remaining 200 censored. Say  $\delta=20,\ \gamma=5,$  and we are interested in the number of survivors out of M=1000 future observations. The figures below illustrate the predictive probability using dpredEG() and rpredEG(), along with a histogram of a random sample taken using rpredEG().

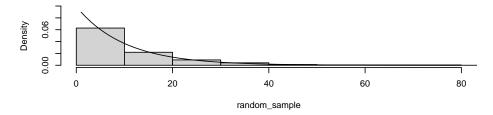

## **Exponential-Gamma Predictive Density**

## **Exponential-Gamma Cumulative Predictive Probability**

## Histogram of Sample with Density Curve Overlay

## 3.3 Poisson-Gamma Model (Hoff p. 43ff)

## 3.3.1 Derivation

[using Hoff's notation and variable names below. Should I convert this to Geisser's  $x^{(N)}, x_{(M)}$  convention for uniformity throughout my thesis?]

Suppose  $Y_1, ..., Y_n | \theta \stackrel{i.i.d.}{\sim} \text{Poisson}(\theta)$  with Gamma prior  $\theta \sim \text{Gamma}(\alpha, \beta)$ . That is,

$$P(Y_1 = y_1, ..., Y_n = y_n | \theta) = \prod_{i=1}^n p(y_i | \theta)$$

$$= \prod_{i=1}^n \frac{1}{y!} \theta^{y_i} e^{-\theta}$$

$$= \left(\prod_{i=1}^n \frac{1}{y!}\right) \theta^{\sum y_i} e^{-n\theta}$$

$$= c(y_1, ..., y_n) \theta^{\sum y_i} e^{-n\theta}$$

and

$$p(\theta) = \frac{\beta^{\alpha}}{\Gamma(\alpha)} \theta^{\alpha - 1} e^{-\beta \theta}, \theta, \alpha, \beta > 0.$$

Then we have posterior distribution

$$p(\theta|y_1, ..., y_n) = \frac{p(y_1, ..., y_n|\theta) p(\theta)}{\int_{\theta} p(y_1, ..., y_n|\theta) p(\theta)}$$

$$= \frac{p(y_1, ..., y_n|\theta) p(\theta)}{p(y_1, ..., y_n)}$$

$$= \frac{1}{p(y_1, ..., y_n)} \theta^{\sum y_i} e^{-n\theta} \frac{\beta^{\alpha}}{\Gamma(\alpha)} \theta^{\alpha-1} e^{-\beta\theta}$$

$$= C(y_1, ..., y_n, \alpha, \beta) \theta^{\alpha+\sum y_i - 1} e^{-(\beta+n)\theta}$$

$$\sim \text{Gamma} \left(\alpha + \sum y_i, \beta + n\right).$$

Here

$$C(y_{1},...,y_{n},\alpha,\beta) = \frac{1}{p(y_{1},...,y_{n})} \cdot \frac{\beta^{\alpha}}{\Gamma(\alpha)}$$

$$= \frac{1}{\int_{\theta} p(y_{1},...,y_{n}|\theta) p(\theta)} \cdot \frac{\beta^{\alpha}}{\Gamma(\alpha)}$$

$$= \frac{1}{\int_{\theta} \left(\prod \frac{1}{y_{i}!}\right) \theta^{\sum y_{i}} e^{-n\theta} \left(\frac{\beta^{\alpha}}{\Gamma(\alpha)}\right) \theta^{\alpha-1} e^{-\beta\theta}} \cdot \left(\frac{\beta^{\alpha}}{\Gamma(\alpha)}\right)$$

$$= \frac{1}{\left(\prod \frac{1}{y_{i}!}\right) \frac{\Gamma(\alpha + \sum y_{i})}{(\beta + n)^{\alpha + \sum y_{i}}} \int_{\theta} \frac{(\beta + n)^{\alpha + \sum y_{i}}}{\Gamma(\alpha + \sum y_{i})} \theta^{\sum y_{i} + \alpha - 1} e^{-(\beta + n)\theta}}$$

$$= \frac{\prod_{i=1}^{n} y_{i}! (\beta + n)^{\alpha + \sum y_{i}}}{\Gamma(\alpha + \sum y_{i})}$$

Call this constant  $C_n$  (for n observations).

Note that an additional observation  $y_{n+1} = \tilde{y}$  the constant becomes

$$C_{n+1} = \frac{\prod_{i=1}^{n+1} y_i! (\beta + n + 1)^{\alpha + \sum_{i=1}^{n+1} y_i}}{\Gamma(\alpha + \sum_{i=1}^{n+1} y_i)}.$$

Also note that the marginal joint distribution of k observations is

$$p(\tilde{y}|y_1,...,y_k) = \frac{1}{C_k} \frac{\beta^{\alpha}}{\Gamma(\alpha)}.$$

For future observation  $\tilde{y}$ , then, we compute predictive distribution

$$\begin{split} p\left(\tilde{y}|y_{1},...,y_{n}\right) &= \frac{p\left(y_{1},...,y_{n},\tilde{y}\right)}{p\left(y_{1},...,y_{n}\right)} = \frac{p\left(y_{1},...,y_{n+1}\right)}{p\left(y_{1},...,y_{n}\right)} = \frac{\frac{1}{C_{n+1}}\frac{\beta^{o}}{p\left(\alpha\right)}}{\frac{1}{C_{n}}\frac{\beta^{o}}{p\left(\alpha\right)}} = \frac{C_{n}}{C_{n+1}} \end{split}$$

$$&= \frac{\prod_{i=1}^{n}y_{i}!(\beta+n)^{\alpha+\sum_{i=1}^{n}y_{i}}}{\Gamma(\alpha+\sum_{i=1}^{n}y_{i})}$$

$$&= \frac{\Gamma(\alpha+\sum_{i=1}^{n+1}y_{i})(\beta+n)^{\alpha+\sum_{i=1}^{n}y_{i}}}{\Gamma(\alpha+\sum_{i=1}^{n+1}y_{i})}$$

$$&= \frac{\Gamma\left(\alpha+\sum_{i=1}^{n+1}y_{i}\right)(\beta+n)^{\alpha+\sum_{i=1}^{n}y_{i}}}{(y_{n+1}!)\Gamma\left(\alpha+\sum_{i=1}^{n}y_{i}\right)(\beta+n+1)^{\alpha+\sum_{i=1}^{n+1}y_{i}}}$$

$$&= \frac{\Gamma\left(\alpha+\sum_{i=1}^{n}y_{i}+\tilde{y}\right)(\beta+n)^{\alpha+\sum_{i=1}^{n}y_{i}}}{(\tilde{y}!)\Gamma\left(\alpha+\sum_{i=1}^{n}y_{i}\right)(\beta+n+1)^{\alpha+\sum_{i=1}^{n}y_{i}+\tilde{y}}}$$

$$&= \frac{\Gamma\left(\alpha+\sum_{i=1}^{n}y_{i}+\tilde{y}\right)(\beta+n+1)^{\alpha+\sum_{i=1}^{n}y_{i}+\tilde{y}}}{\Gamma(\tilde{y}+1)\Gamma(\alpha+\sum_{i=1}^{n}y_{i})} \cdot \left(\frac{\beta+n}{\beta+n+1}\right)^{\alpha+\sum_{i=1}^{n}y_{i}+\tilde{y}} \cdot \left(\frac{1}{\beta+n+1}\right)^{\tilde{y}}$$

This is a negative binomial distribution:  $\tilde{y} \sim NB(\alpha + \sum y_i, \beta + n)$ , for which

$$E\left[\tilde{Y}|y_1,...,y_n\right] = \frac{a+\sum y_i}{b+n} = E\left[\theta|y_1,...,y_n\right];$$

$$\operatorname{Var}\left[\tilde{Y}|y_1,...,y_n\right] = \frac{a+\sum y_i}{b+n} \frac{b+n+1}{b+n}$$

$$= \operatorname{Var}\left[\theta|y_1,...,y_n\right] \times (b+n+1)$$

$$= E\left[\theta|y_1,...,y_n\right] \times \frac{b+n+1}{b+n}$$

[Showing here that it is indeed a NB distribution]

$$\theta \sim NB(\alpha, \beta) \Rightarrow p(\theta) = \begin{pmatrix} \theta + \alpha - 1 \\ \alpha - 1 \end{pmatrix} \left( \frac{\beta}{\beta + 1} \right)^{\alpha} \left( \frac{1}{\beta + 1} \right)^{\theta}$$

$$\tilde{y} \sim NB\left(\alpha + \sum y_i\right), \beta + n\right) \Rightarrow p(\tilde{y}) = \begin{pmatrix} \tilde{y} + \alpha + \sum y_i - 1 \\ \alpha + \sum y_i - 1 \end{pmatrix} \left(\frac{\beta + n}{\beta + n + 1}\right)^{\alpha + \sum y_i} \left(\frac{1}{\beta + n + 1}\right)^{\tilde{y}}$$

$$= \frac{(\alpha + \sum y_i + \tilde{y} - 1)!}{(\alpha + \sum y_i - 1)! (\tilde{y})!} \left(\frac{\beta + n}{\beta + n + 1}\right)^{\alpha + \sum y_i} \left(\frac{1}{\beta + n + 1}\right)^{\tilde{y}}$$

$$= \frac{\Gamma(\alpha + \sum y_i + \tilde{y})}{\Gamma(\alpha + \sum y_i) \Gamma(\tilde{y} + 1)} \left(\frac{\beta + n}{\beta + n + 1}\right)^{\alpha + \sum y_i} \left(\frac{1}{\beta + n + 1}\right)^{\tilde{y}}$$

[This is the result in Hoff. The straightforward derivation below is off by a constant multiple. Need to figure out what went awry.]

$$\begin{split} p\left(\tilde{y}|y_{1},...,y_{n}\right) &= \int_{0}^{\infty} p\left(\tilde{y}|\theta,y_{1},...,y_{n}\right) p\left(\theta|y_{1},...,y_{n}\right) d\theta \\ &= \int p\left(\tilde{y}|\theta\right) p\left(\theta|y_{1},...,y_{n}\right) d\theta \\ &= C \int \left(\frac{1}{\tilde{y}!} \theta^{\tilde{y}} e^{-\theta}\right) \theta^{\alpha + \sum y_{i} - 1} e^{-(\beta + n)\theta} d\theta \\ &= \frac{C}{\tilde{y}!} \int \theta^{\tilde{y} + \alpha + \sum y_{i} - 1} e^{-(\beta + n + 1)\theta} d\theta \\ &= \frac{C\Gamma\left(\tilde{y} + \alpha + \sum y_{i}\right)}{\Gamma\left(\tilde{y} + 1\right)\left(\beta + n + 1\right)^{\tilde{y} + \alpha + \sum y_{i}}} \int \frac{(\beta + n + 1)^{\tilde{y} + \alpha + \sum y_{i}}}{\Gamma\left(\tilde{y} + \alpha + \sum y_{i}\right)} \theta^{\tilde{y} + \alpha + \sum y_{i} - 1} e^{-(\beta + n + 1)\theta} d\theta \\ &= C \cdot \frac{\Gamma\left(\tilde{y} + \alpha + \sum y_{i}\right)}{\Gamma\left(\tilde{y} + 1\right)\left(\beta + n + 1\right)^{\tilde{y} + \alpha + \sum y_{i}}} \\ &= \frac{\prod_{i=1}^{n} y_{i}!(\beta + n)^{\alpha + \sum y_{i}}}{\Gamma(\alpha + \sum y_{i})} \cdot \frac{\Gamma\left(\tilde{y} + \alpha + \sum y_{i}\right)}{\Gamma\left(\tilde{y} + 1\right)\left(\beta + n + 1\right)^{\tilde{y} + \alpha + \sum y_{i}}} \\ &= \prod_{i=1}^{n} y_{i}! \cdot \frac{\Gamma\left(\tilde{y} + \alpha + \sum y_{i}\right)}{\Gamma\left(\tilde{y} + 1\right)\Gamma\left(\alpha + \sum y_{i}\right)} \cdot \left(\frac{\beta + n}{\beta + n + 1}\right)^{\alpha + \sum y_{i}} \cdot \left(\frac{1}{\beta + n + 1}\right)^{\tilde{y}} \end{split}$$

#### Hoff p.47:

- b is interpreted as the number of prior observations
- a is interpreted as the sum of counts from b prior observations

Hoff p. 49 (Birth rate example): a = 2, b = 1.

#### 3.3.2 R Implementation

This result has been used to create standard format R functions dpredPG(), ppredPG(), and rpredPG() for the Poisson-Gamma distribution for density, cumulative probability, and random sampling, respectively (see appendix). These functions are exercised in the following example.

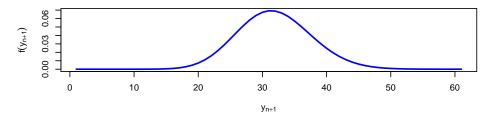

Developing the random sample function rpredPG(): I need to establish the support of the predictive distribution  $f_x$  from which to sample. the uniroot() function is not working because it keeps feeding non-integer values to dnbinom(). Strategy: a modified bisection method as follows:

- 1. set a desired tolerance  $\epsilon$ .
- 2. Find the expected value  $E_x$  (closed formula, see above).
- 3. Step to the right of  $E_x$  by whole integers, in the sequence  $E_x + \{1, 2, 4, ... 2^n\}$ , stopping at  $U = f_x (E_x + 2^n) < 0$ . This is the upper bound for the bisection method.
- 4. Bisect the interval, rounding to the nearest integer. Call the resulting mid-interval number B.
- 5. If B is positive, test whether  $0 \le f_x(B) \le \epsilon$ . If so, DONE. If not:
- 6. Establish new interval, choosing endpoints from  $E_x$ , B, and U so that the interval straddles 0, and repeat the steps until the condition in step 5 is reached.

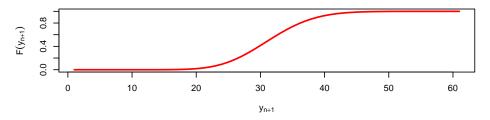

#### **3.3.3** Example

Suppose we have 10 prior observations with counts 27, 79, 21, 100, 8, 4, 37, 15, 3, 97. Let  $\alpha = 11$  and  $\beta = 3$ . For  $\tilde{y} = 1 : 100$  possible future occurrences, the figures below show the predictive distribution from dpredPG(), the cumulative distribution from ppredPG(), and a histogram of random draws from rpredPG().

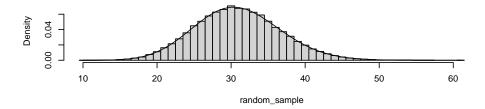

#### Poisson-Gamma Predictive Density

#### Poisson-Gamma Cumulative Predictive Probability

#### Histogram of Sample with Density Curve Overlay

## 3.4 Normal Observation with Normal-Inverse Gamma Prior

## 3.4.1 One sample

## **3.4.1.1 Derivation** [Hoff p. 69ff]

Let  $\{Y_1, ..., Y_n | \theta, \sigma^2\} \stackrel{i.i.d.}{\sim} N(\theta, \sigma^2)$ . Then the joint sampling density is

$$p(y_1, ..., y_n | \theta, \sigma^2) = \prod_{i=1}^n p(y_i | \theta, \sigma^2)$$
$$= \prod_{i=1}^n \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2} \left(\frac{y_i - \theta}{\sigma}\right)^2}$$
$$= \left(2\pi\sigma^2\right)^{-n/2} e^{-\frac{1}{2} \sum_{i=1}^n \left(\frac{y_i - \theta}{\sigma}\right)^2}.$$

It can be shown that  $\{\sum y_i^2, \sum y_i\}$  and hence  $\{\bar{y}, s^2\}$  are sufficient statistics, where  $\bar{y} = \sum y_i/n$  and  $s^2 = \sum (y_i - \bar{y})^2/(n-1)$ .

:

Following Hoff (p. 74ff), for joint inference on both  $\theta$  and  $\sigma$ , assume priors

$$\frac{1}{\sigma^2} \sim \operatorname{gamma}(\nu_0/2, \nu_0 \sigma_0^2/2)$$

$$\theta | \sigma^2 \sim \text{normal}(\mu_0, \sigma^2/\kappa_0)$$

where  $(\sigma_0^2, \nu_0)$  are the sample variance and sample size of prior observations, and  $(\mu_o, \kappa_0)$  are the sample mean and sample size of prior observations.

Are there different sets of prior observations for the two different prior distributions? I.e. does  $\nu_0 = \kappa_0$ ?

Note:  $\mu_0$ ,  $\kappa_0$ ,  $\nu_0$ , and  $\sigma_0^2$  come from prior knowledge. [in the Hoff example (Midge Wing Length),  $\kappa_0$  and  $\nu_0$  are both set to 1 so that "our prior distributions are only weakly centered around these estimates from other populations."]

From this we derive joint posterior

$$\{\theta|y_1,...,y_n,\sigma^2\} \sim \operatorname{normal}(\mu_n,\sigma^2/\kappa_n)$$

$$\left\{\sigma^2|y_1,...,y_n\right\}\sim \text{inverse-gamma}\left({}^{\nu_n}\!/_2,\sigma_n^2\nu_n/_2\right).$$

where

$$\kappa_n = \kappa_0 + n$$

$$\mu_n = \frac{\kappa_0 \mu_0 + n\bar{y}}{\kappa_n}$$

$$\nu_n = \nu_0 + n$$

$$\sigma_n^2 = \frac{1}{\nu_n} \left[ \nu_0 \sigma_0^2 + (n-1)s^2 + \frac{\kappa_0 n}{\kappa_n} (\bar{y} - \mu_0)^2 \right].$$

Here  $\bar{y} = \frac{1}{n} \sum_{i=1}^{n} y_i$  is the sample mean and  $s^2 = \frac{1}{n-1} \sum_{i=1}^{n} (y_i - \bar{y})^2$  is the sample variance.

From the joint posterior distribution we generate marginal samples by means of the Monte Carlo method (Hoff, p. 77):

$$\begin{split} \sigma^{2(1)} \sim \text{inverse-gamma} \left(\nu_n/2, \sigma_n^2 \nu_n/2\right), & \theta^{(1)} \sim \text{normal} \left(\mu_n, \sigma^{2(1)}/\kappa_n\right) \\ \vdots & \vdots \\ \sigma^{2(S)} \sim \text{inverse-gamma} \left(\nu_n/2, \sigma_n^2 \nu_n/2\right), & \theta^{(S)} \sim \text{normal} \left(\mu_n, \sigma^{2(S)}/\kappa_n\right) \end{split}$$

For prediction of future  $\tilde{y}|y_1,...,y_n,\theta,\sigma^2$ , generate  $\tilde{y}_i \sim \text{normal}(\theta^{(i)},\sigma^{2(i)})$ .

**3.4.1.2 R Implementation** Standard format R functions dpredNormIG(), ppredNormIG(), and rpredNormIG() have been created for the Normal-Inverse Gamma distribution for density, cumulative probability, and random sampling, respectively (see appendix). For the random sampler rpredNormIG(), the Monte-Carlo method described above was directly employed. The predictive density and cumulative density functions depend on the random sample, and utilize Kernel Density Estimation (KDE) and R's built-in density() function. The KDE is computed by definition, using a normal kernel:

$$\hat{f}_K(x) = \frac{1}{n} \sum_{i=1}^n \frac{1}{h} K\left(\frac{x - X_i}{h}\right),$$

where

 $X_i$  is the random sample generated using rpredNormIG()

K is Normal(0,1)

h is the bandwidth from R's density() function (that is,  $h = \text{density}(X_i)$ \$bw)

These functions are exercised in the following example.

Example (Hoff p. 72ff, using data from Grogan and Wirth (1981)): Midge wing length

Grogan and Wirth (1981) provide 9 measurements of midge wing length, in millimeters:  $y = \{1.64, 1.7, 1.72, 1.74, 1.82, 1.82, 1.82, 1.90, 2.08\}$ . Prior studies suggest values  $\mu_0 = 1.9$  and  $\sigma_0^2 = 0.01$ . We choose  $\kappa_0 = \nu_0 = 1$  "...so that our prior distributions are only weakly centered around these estimates from other populations" (Hoff p. 76). We compute

$$\bar{y} = 1.804$$

$$\operatorname{var}(y) = 0.0169$$

$$\kappa_n = 1 + 9 = 10$$

$$\mu_n = \frac{1 \cdot 1.9 + 9 \cdot 1.804}{10} = 1.814$$

$$\nu_n = 1 + 9 = 10$$

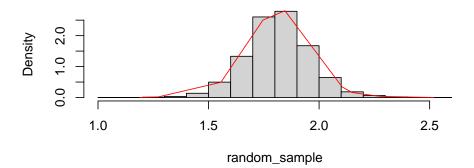

$$\sigma_n^2 = \frac{1}{10} \left[ 1 \cdot 0.01 + (9 - 1) \cdot 0.0169 + \frac{1 \cdot 9}{10} (1.804 - 1)^2 \right] = 0.0153$$

Thus  $\nu_n/2 = 5$  and  $nu_n \sigma_n^2/2 = 0.7662$  and we have posteriors

$$\left\{\theta|y_1,...,y_n,\sigma^2\right\} \sim \text{normal}\left(1.814,\sigma^2/\text{10}\right)$$
 
$$\left\{\sigma^2|y_1,...,y_n\right\} \sim \text{inverse-gamma}(5,0.7662)$$

posteriors given Jeffrey's Prior:

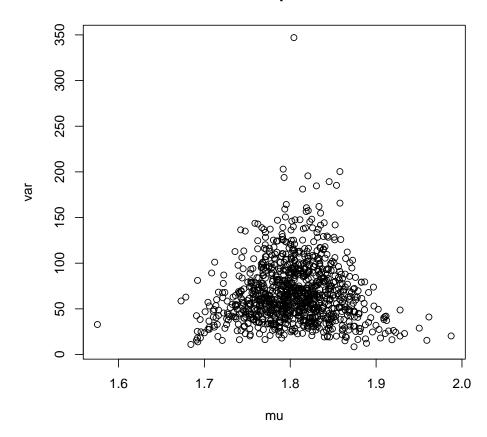

$$\{1/\sigma^2|y_1,...,y_n\} \sim \text{gamma}\left(\frac{n}{2},\frac{n}{2}\frac{1}{n}\sum (y_i - \bar{y})^2\right)$$

same as

$$\{1/\sigma^2|y_1,...,y_n\} \sim \operatorname{gamma}\left(\frac{n}{2},\frac{1}{2}\sum (y_i - \bar{y})^2\right)$$
  
 $\{\theta|\sigma^2, y_1,...,y_n\} \sim \operatorname{normal}\left(\bar{y},\frac{\sigma^2}{n}\right)$
